INTRODUCTION

It is a model that predicts the total ride duration of taxi trips in New York City. The primary dataset is released by the NYC Taxi and Limousine Commission, which include pickup time, geo-coordinates, number of passengers, and several other variables.

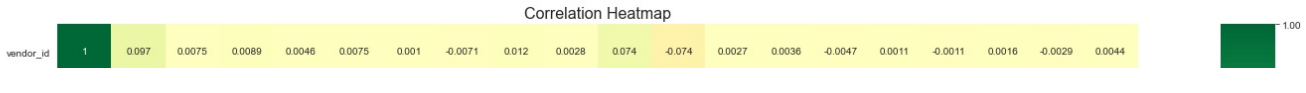
Correlation Analysis

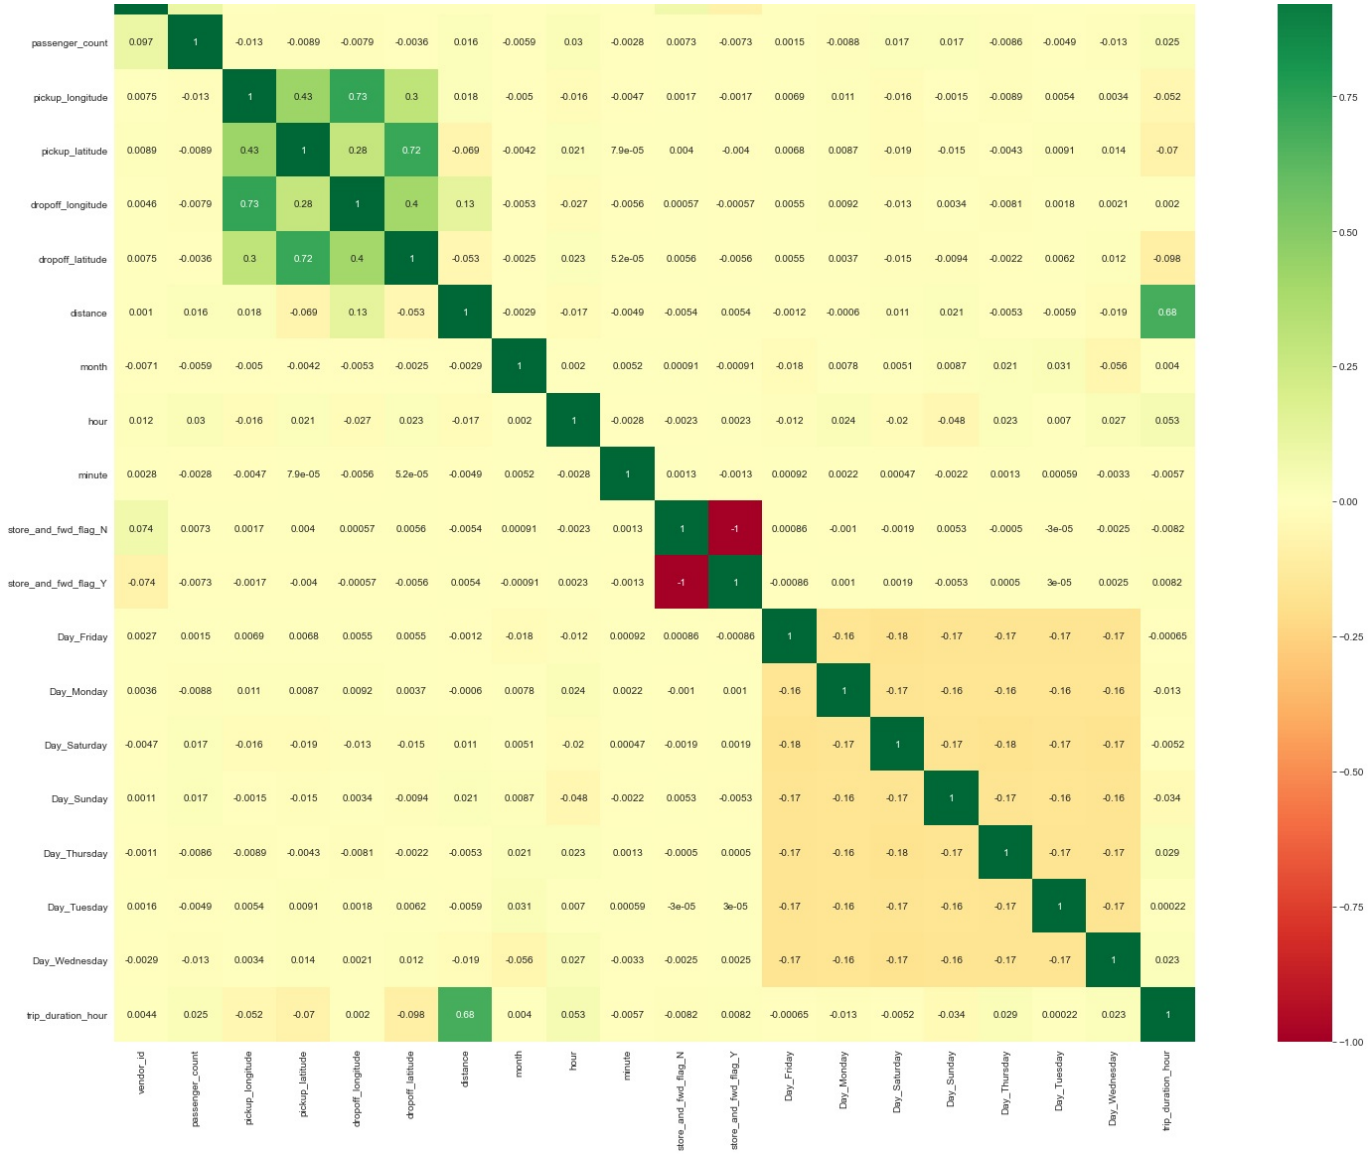
It is a method of statistical evaluation used to study the strength of a relationship between two or more, numerically measured, continuous variables. This analysis is useful to check if there are possible connections between variables.

Heatmap:

In [81]:
```
plt.figure (figsize= (30,20))

sns.heatmap(trip_data.corr(), cmap='RdYlGn', annot=True,vmin=-1, vmax=1, square=True)
plt.title("Correlation Heatmap", fontsize=16)
plt.show()
```





In [82]:

```
from matplotlib import legend
# Function for evaluation metric for regression

  ''' Take the different set of parameter and prints evaluation metrics '''
  MSE=round(mean_squared_error(y_true=yt,y_pred=yp),4)
  RMSE=(np.sqrt(MSE))
  R2=(r2_score(y_true=yt,y_pred=yp))
  Adjusted_R2=(1-(1-r2_score(yt, yp))*((Xt.shape[0]-1)/(Xt.shape[0]-Xt.shape[1]-1)))
  if disp=="on":
    print("MSE :",MSE,"RMSE :", RMSE)
    print("R2 :",R2,"Adjusted R2 :",Adjusted_R2)

  #Plotting Actual and Predicted Values
  plt.figure(figsize=(18,6))
  plt.plot((yp)[:100])
  plt.plot((np.array(yt)[:100]))
  plt.legend(["Predicted","Actual"])
  plt.title('Actual and Predicted Time Duration')

  return (MSE,RMSE,R2,Adjusted_R2)
```

Linear Regression

Linear regression analysis is used to predict the value of a variable based on the value of another variable. The variable you want to predict is called the dependant variable. The variable used to predict the other variable value is called the independent variable.

In [84]:

```
from sklearn.linear_model import LinearRegression

reg = LinearRegression().fit(X_train, y_train)
reg.score(X_train, y_train)
```

We conclude that Gradient Boosting perform well.

Conclusion

Objective:

- We observe that both models show somewhat similar learning rate but with visible differences in error rates.
- Gradient boosting performed very well out of all the models
- XGBoost training curve on the other hand starts quite low and further improves with the increase in the training size and it too plateau towards the end.
- Validation curve seems to show similar trend in both the models i.e. starts very high but improves with the training size with some differences in error rate i.e. XGBoost curve learning is quite fast and more accurate as compared to the RF one.
- Both the models seems to suffer from high variance since the training curve error is very less in both the models.
- The large gap at the end also indicates that the model suffers from quite a low bias i.e. overfitting the training data.
- Also, both the model's still has potential to decrease and converge towards the training curve by the end.

End Notes:

We discussed a variety of machine learning development cycle topics in this project. We found that the exploration of the data and variable analysis is a crucial part of the process and should be carried out for a complete knowledge of the data. While exploring, we also cleansed

the data because some outliers needed to be dealt with before feature engineering. Additionally, we used feature engineering to filter out and collect only the best features—those that are more important and accounted for the majority of the variance in the dataset. Finally, we trained the models using the featureset that produced the best results.

Improvement:

- Add more training instances to improve validation curve in the XGBoost model.
- Increase the regularization for the learning algorithm. This should decrease the variance and increase the bias towards the validation curve.
- Reduce the numbers of features in the training data that we currently use. The algorithm will still fit the training data very well, but due to the decreased number of features, it will build less complex models. This should increase the bias and decrease the variance.
